

AI Travel Agent

Problem Statement

The Challenge

Planning a trip often requires users to search across multiple websites for destinations, transportation, accommodations, weather conditions, budgets, and local attractions. This process is time-consuming and can lead to incomplete or inaccurate travel plans.

Travelers need a single intelligent assistant that can provide personalized recommendations, generate itineraries, estimate travel costs, and answer travel-related questions in real time.

Objective

Build an AI-powered Travel Agent that helps users plan trips efficiently by providing destination recommendations, itinerary generation, budget estimation, travel guidance, and personalized suggestions based on user preferences.

Proposed Solution

The AI Travel Agent uses Large Language Models, Retrieval-Augmented Generation (RAG), and travel knowledge databases to understand user requirements and generate customized travel plans. The system can recommend destinations, suggest accommodations, provide local attraction information, and optimize itineraries according to budget and travel preferences.

Technologies Used

- Langflow
- IBM Granite Model
- IBM Watsonx.ai
- IBM Cloud
- RAG (Retrieval-Augmented Generation)
- FAISS/Chroma Vector Database

Expected Outcome

A smart travel assistant capable of delivering personalized travel recommendations, trip itineraries, budget estimates, and travel information through an interactive conversational interface.
